d.mandic@imperial.ac.uk, URL: www.commsp.ee.ic.ac.uk/~mandic

This lecture \hookrightarrow Time Series Modelling and Prediction

Q: Have you ever considered what the following tasks have in common?

- Forecasting of financial data
- Supply-demand modelling (e.g. electricity or air-ticket pricing)
- Modelling of COVID-19 spread
- Weather forecasting and modelling in astronomy (e.g. sunspots)
- Word generation by Large Language Models such as ChatGPT

A: These are time series of which the signal generating mechanisms are largely unknown or untractable. We need to make inference from such data based on historical observations (autoregression) – subject of this Lecture.

London

Aims of this lecture

- $\circ~$ To introduce linear stochastic models for real world data
- $\circ~$ Learn how stochastic models shape up the spectrum of white noise
- Understand how stochastic processes are created, and to get familiarised with the autocorrelation, variance and power spectrum of such processes
- Learn how to derive the parameters of linear stochastic ARMA models
- Introduce special cases: autoregressive (AR), moving average (MA)
- Stability conditions and model order selection (partial correlations)
- Optimal model order selection criteria (MDL, AIC, ...)
- Apply stochastic modelling to real world data (speech, environmental, finance), and address the issues of under- and over-modelling

This material is a first fundamental step for real-world time series analysis

Example 1: Assessing the nature of a signal from its ACF

Windowed clean signal, signal in WGN, signal with DC offset (see also Lecture 1)

Which disturbance is more detrimental: deterministic DC or stochastic noise

Justification \hookrightarrow Wold decomposition theorem

(Existence theorem, also mentioned in your coursework)

Wold's decomposition theorem plays a central role in time series analysis, and explicitly proves that any covariance–stationary time series can be decomposed into two different parts: **deterministic** (such as a sinewave) and **stochastic** (filtered WGN).

Therefore, a general process can be written as a sum of two processes

$$\begin{split} x[n] &= x_p[n] + x_r[n] = x_p[n] + \sum_{j=1}^q b_j w[n-j] \qquad w \rightsquigarrow \text{white process} \\ \Rightarrow x_r[n] \quad &\hookrightarrow \quad \text{regular random process} \\ \Rightarrow x_p[n] \quad &\hookrightarrow \quad \text{predictable process, with } x_r[n] \qquad \perp x_p[n], \\ E\{x_r[m]x_p[n]\} &= 0 \end{split}$$

→ we can treat **separately** the **predictable** part (e.g. a deterministic sinusoidal signal) and the **random** signal.

Our focus will be on the modelling of the random component NB: Recall the difference between shift–invariance and time–invariance

How do we model a real world signal?

Suppose the measured real world signal has e.g. a bandpass (any other) power spectrum We desire to describe the whole long signal with very few parameters

- 1. Can we model first and second statistics of real world signal by shaping up the white noise spectrum using some transfer function?
- 2. Does this produce the same second order properties (mean, variance, ACF, spectrum) for any white noise input?

Can we use this linear stochastic model for prediction?

Towards linear stochastic processes

Wold's theorem implies that any purely non-deterministic covariance-stationary

process can be arbitrarily well approximated by an ARMA process

Therefore, the general form for the power spectrum of a WSS process is $_{N}^{N}$

$$P_x(e^{j\omega}) = \sum_{k=1}^{N} \alpha_k \delta(\omega - \omega_k) + P_{x_r}(e^{j\omega})$$

We are interested in processes generated by **filtering white noise with a linear shift-invariant filter** that has a rational system function. This class of digital filters includes the following system functions:

- Autoregressive (AR) \rightarrow all pole system \rightarrow H(z) = 1/A(z)
- Moving Average (MA) \rightarrow all zero system \rightarrow H(z) = B(z)
- Autoregressive Moving Average (ARMA) \rightarrow poles and zeros $\rightarrow H(z) = B(z)/A(z)$

Definition: A covariance-stationary process x[n] is called **(linearly)** deterministic if p(x[n] | x[n-1], x[n-2], ...) = x[n].

A stationary deterministic process, $x_p[n]$, can be predicted correctly (with zero error) using the entire past, $x_p[n-1], x_p[n-2], x[n-3], \ldots$

Example 2: Second-order all-pole systems and sinewave

 $p_1 = 0.999 exp(j\pi/4)$, $p_2 = 0.9 exp(j\pi/4)$, $p_3 = 0.9 exp(j7\pi/12)$

for the sinewave $\rho = 1 \implies H(z) = \frac{1}{1 - 2\cos(\theta)z^{-1} + z^{-2}} = \frac{1}{1 + a_1 z^{-1} + a_2 z^{-2}}$

Improve the second seco

Example 2: Sinewave revisited, is it det. or stoch.?

Is a sinewave best described as nonlinear deterministic or linear stochastic?

How can we categorise real-world measurements?

where would you place a DC level in WGN, $x[n] = A + w[n], \quad w \sim \mathcal{N}(0, \sigma_w^2)$

(a) Noisy oscillations, (b) Nonlinearity and noisy oscillations, (c) Random nonlinear process

(? left) Route to chaos, (? top) stochastic chaos, (? middle) mixture of sources

Our lecture is about ARMA models (linear stochastic)

How about observing the signal through a nonlinear sensor?

Spectrum of ARMA models (look also at Recap slides)

recall that two conjugate complex poles of A(z) give one peak in the spectrum

$ACF \equiv PSD$ in terms of the information available

In ARMA modelling we filter white noise w[n] (so called driving input) with a causal linear shift-invariant filter with the transfer function H(z), a rational system function with p poles and q zeros given by

$$X(z) = H(z)W(z) \quad \Leftrightarrow \quad H(z) = \frac{B_q(z)}{A_p(z)} = \frac{\sum_{k=0}^q b_k z^{-k}}{1 + \sum_{k=1}^p a_k z^{-k}}$$

For a stable H(z), the **ARMA(p,q)** stochastic process x[n] will be wide-sense stationary. For the **driving noise** power $P_w = \sigma_w^2$, the power of the stochastic process x[n] is

(recall: power at the output of a linear system $P_y = |H(z)|^2 P_x = H(z)H^*(z)P_x$)

$$P_{x}(z) = \sigma_{w}^{2} \frac{B_{q}(z)B_{q}(z^{-1})}{A_{p}(z)A_{p}(z^{-1})} \quad \Rightarrow \quad P_{z}(e^{j\theta}) = \sigma_{w}^{2} \frac{\left|B_{q}(e^{j\theta})\right|^{2}}{\left|A_{p}(e^{j\theta})\right|^{2}} = \sigma_{w}^{2} \frac{\left|B_{q}(\omega)\right|^{2}}{\left|A_{p}(\omega)\right|^{2}}$$

Notice that " $(\cdot)^*$ " in analogue frequency corresponds to " z^{-1} " in "digital freq."

Example 3: Can the shape of power spectrum tell us about the order of the polynomials B(z) and A(z)?

Plot the power spectrum of an ARMA(2,2) process for which

$$\circ\,$$
 the zeros of $H(z)$ are $z=0.95e^{\pm\jmath\pi/2}$

 $\circ~$ poles are at $z=0.9e^{\pm\jmath 2\pi/5}$

Solution: The system function is (poles and zeros – resonance & sink)

Example 4: Power spectrum of real-world Sunspot data

Sunspot numbers and their PSD \rightsquigarrow even their AR(2) linear model is powerful!

Recorded from about 1700 onwards

This signal is random, as sunspots originate from the explosions of helium on the Sun. Still, the number of sunspots obeys a relatively simple model and is predictable, as shown later in the Lecture.

Difference equations \hookrightarrow the ACF follows the data model!

(for convenience, a slight abuse in notation from A(z) to the autoregressive part)

Since X(z) = H(z)W(z), the random processes x[n] and w[n] are related by a linear difference equation with constant coefficients, given by

$$H(z) = \frac{B(z)}{A(z)} = \frac{\sum_{k=0}^{q} b_k z^{-k}}{1 - \sum_{k=1}^{p} a_k z^{-k}} \quad \leftrightarrow \operatorname{ARMA}(p,q) \leftrightarrow \quad x[n] = \sum_{\substack{l=1\\autorearessive}}^{p} a_l x[n-l] + \sum_{\substack{l=0\\box{moving average}}}^{q} b_l w[n-l]$$

Notice that the autocorrelation function of x[n] and crosscorrelation between the stochastic process x[n] and the driving input w[n] follow the same difference equation, i.e. if we multiply both sides of the above equation by x[n-k] and take the statistical expectation, we have

$$r_{xx}(k) = \sum_{\substack{l=1\\easy \text{ to calculate}}}^{p} a_l r_{xx}(k-l) + \sum_{\substack{l=0\\can \text{ be complicated}}}^{q} b_l r_{xw}(k-l) \qquad \text{(see also Slide 18)}$$

Since x is WSS, it follows that x[n] and w[n] are jointly WSS

General linear processes: Stationarity and invertibility

Can we tell anything about the process x from the coefficients a, b (cf. h in FIR)

Consider a linear stochastic process \hookrightarrow output from a linear filter, driven by WGN, denoted by w[n]. (NB: Here w is "input" and x "output")

$$x[n] = w[n] + b_1 w[n-1] + b_2 w[n-2] + \dots = w[n] + \sum_{j=1}^{\infty} b_j w[n-j]$$

that is, a weighted sum of past samples of driving white noise w[n]. For this process to be a valid stationary process, the coefficients must be **absolutely summable**, that is $\sum_{j=0}^{\infty} |b_j| < \infty$.

This also implies that under stationarity conditions, x[n] is also a weighted sum of past values of x, plus an added shock w[n], that is

$$x[n] = a_1 x[n-1] + a_2 x[n-2] + \dots + w[n]$$
 (see also Slide 30)

- \circ Linear Process is *stationary* if $\sum_{j=0}^{\infty} |b_j| < \infty$
- Linear Process is *invertible* if $\sum_{j=0}^{\infty} |a_j| < \infty$

Recall that $H(\omega) = \sum_{n=0}^{\infty} h(n) e^{-j\omega n} \quad \rightarrow \text{for } \omega = 0 \quad \Rightarrow H(0) = \sum_{n=0}^{\infty} h(n)$

Autoregressive processes (pole–only)

A general AR(p) process (autoregressive of order p) is given by

$$x[n] = a_1 x[n-1] + \dots + a_p x[n-p] + w[n] = \sum_{i=1}^p a_i x[n-i] + w[n] = \mathbf{a}^T \mathbf{x}[n] + w[n]$$

Observe the auto-regression in $\{x[n]\} \hookrightarrow$ the past of x is used to generate the future

Duality between the AR and MA processes:

For example, the first order autoregressive process, AR(1),

$$x[n] = a_1 x[n-1] + w[n] \quad \Leftrightarrow \quad \sum_{j=0}^{\infty} b_j w[n-j]$$

has an MA representation, too (right hand side above).

This follows from the duality between IIR and FIR filters.

Example 5: Statistical properties of AR processes

Drive the AR(4) model from Example 6 with two different WGN realisations $\sim \mathcal{N}(0, 1)$

r = wgn(2048,1,1); a = [2.2137, -2.9403, 2.1697, -0.9606]; a = [1 -a]; x = filter(1,a,r); xacf = xcorr(x); xpsd = abs(fftshift(fft(xacf)));

Imperial College London © D. P. Mandic • The time domain random AR(4) processes look different

• The ACFs and PSDs are exactly the same (2nd-order stats)!

• This signifies the importance of our statistical approach

ACF and normalised ACF of AR proc. (see Appendix 3) Key: ACF has the same form as the AR process in hand!

To obtain the autocorrelation function of an AR process, multiply the above equation by x[n-k] to obtain (recall that r(-m) = r(m))

$$x[n-k]x[n] = a_1x[n-k]x[n-1] + a_2x[n-k]x[n-2] + \cdots + a_px[n-k]x[n-p] + x[n-k]w[n]$$

Notice that $E\{x[n-k]w[n]\}$ vanishes when k > 0. Therefore, we have

$$r_{xx}(0) = a_1 r_{xx}(1) + a_2 r_{xx}(2) + \dots + a_p r_{xx}(p) + \sigma_w^2, \qquad k = 0$$

$$r_{xx}(k) = a_1 r_{xx}(k-1) + a_2 r_{xx}(k-2) + \dots + a_p r_{xx}(k-p), \qquad k > 0$$

On dividing throughout by $r_{xx}(0)$ we obtain

$$\rho(k) = a_1 \rho(k-1) + a_2 \rho(k-2) + \dots + a_p \rho(k-p) \quad k > 0$$

Quantities $\rho(k)$ are called **normalised correlation coefficients**

Variance and spectrum of AR processes

Variance:

For k = 0, the contribution from the term $E\{x[n-k]w[n]\}$ is σ_w^2 , and

$$r_{xx}(0) = a_1 r_{xx}(-1) + a_2 r_{xx}(-2) + \dots + a_p r_{xx}(-p) + \sigma_w^2$$

Divide by $r_{xx}(0) = \sigma_x^2$ to obtain

$$\sigma_x^2 = \frac{\sigma_w^2}{1 - \rho_1 a_1 - \rho_2 a_2 - \dots - \rho_p a_p}$$

Power spectrum: (recall that $P_{xx} = |H(z)|^2 P_{ww} = H(z)H^*(z)P_{ww}$, the expression for the output power of a linear system \rightarrow see Appendix)

$$P_{xx}(f) = \frac{2\sigma_w^2}{\left|1 - a_1 e^{-\jmath 2\pi f} - \dots - a_p e^{-\jmath 2\pi p f}\right|^2} \qquad 0 \le f \le 1/2$$

Fro more detail: "Spectrum of Linear Systems" from Lecture 1: Background

Example 6a: AR(p) signal generation

Consider an AR(4) process with coeff. a = [2.2137, -2.9403, 2.1697, -0.9606]

- Generate the input signal **x** by filtering white noise through the AR filter
- \circ Estimate the PSD of x based on a fourth-order AR model
- Careful! The Matlab routines require the AR coeff. \mathbf{a} in the format $\mathbf{a} = [1, -a_1, \dots, -a_p]$

Notice the dependence on data length

Solution:

```
randn('state',1);
x = filter(1,a,randn(256,1)); % AR system output
pyulear(x,4)
```

% Fourth-order estimate

Example 6b: Alternative AR power spectrum calculation (an alternative function in Matlab)

Consider the AR(4) system given by x[n] = 2.2137x[n-1] - 2.9403x[n-2] + 2.1697x[n-3] - 0.9606x[n-4] + w[n]a = [1 -2.2137 2.9403 -2.1697 0.9606]; % AR filter coefficients freqz(1,a) % AR filter frequency response title('AR System Frequency Response')

Key: Finding AR coefficients \hookrightarrow the Yule–Walker eqns

(there are several similar forms – we follow the most concise one)

Recall that we have already calculated the autocorrelation function (ACF) which follows the same form as the AR(p) model as the data, that is

$$r_{xx}(k) = a_1 r_{xx}(k-1) + a_2 r_{xx}(k-2) + \dots + a_p r_{xx}(k-p), \qquad k > 0$$

Then, with the known $r_{xx}(0), \ldots, r_{xx}(p-1)$, we can build a system of p equations with p unknowns (a_1, \ldots, a_p) , and solve for a_1, \ldots, a_p , that is

$$r_{xx}(1) = a_1 r_{xx}(0) + a_2 r_{xx}(1) + \dots + a_p r_{xx}(p-1)$$

$$r_{xx}(2) = a_1 r_{xx}(1) + a_2 r_{xx}(0) + \dots + a_p r_{xx}(p-2)$$

$$\vdots = \vdots$$

$$r_{xx}(p) = a_1 r_{xx}(p-1) + a_2 r_{xx}(p-2) + \dots + a_p r_{xx}(0)$$

Their solution gives us the set of **autoregressive parameters**, a_1, \ldots, a_p , or $\mathbf{a} = [a_1, \ldots, a_p]^T$, which build the AR(p) model and **generate an AR(p) process.**

Imperial College London © D. P. Mandic

A vector-matrix form of the Yule-Walker equations

The above set of Yule–Walker equations can be expressed in a compact vector–matrix form

$$\mathbf{r}_{xx} = \mathbf{R}_{xx}\mathbf{a}$$
 $\mathbf{a} = [a_1, a_2, \dots, a_p]^T$

since

$$\mathbf{R}_{xx} = \begin{bmatrix} r_{xx}(0) & r_{xx}(1) & \cdots & r_{xx}(p-1) \\ r_{xx}(1) & r_{xx}(0) & \cdots & r_{xx}(p-2) \\ \vdots & \vdots & \ddots & \vdots \\ r_{xx}(p-1) & r_{xx}(p-2) & \cdots & r_{xx}(0) \end{bmatrix} \text{ and } \mathbf{r}_{xx} = \begin{bmatrix} r_{xx}(1) \\ r_{xx}(2) \\ \vdots \\ r_{xx}(p) \end{bmatrix}$$

The ACF matrix \mathbf{R}_{xx} is positive definite (Toeplitz) which guarantees matrix inversion, so that the solution for the unknown AR(p) coeficients, a_1, \ldots, a_p , becomes

$$\mathbf{a} = \mathbf{R}_{xx}^{-1} \mathbf{r}_{xx}$$

Example 7: Find the parameters of an AR(2) process, x(n), generated by x[n] = 1.2x[n-1] - 0.8x[n-2] + w[n]

Coursework: comment on the shape of the ACF for large lags

Example 8: Advantages of model-based analysis

Consider the PSDs for different realisations of the AR(4) process from Example 5

- The different realisations of the AR(4) process (based on different driving WGNs) lead to different Empirical PSD's (in thin black)
- The theoretical PSD from the model is consistent regardless of the data (in thick red)

```
N = 1024;
w = wgn(N,1,1);
a = [2.2137, -2.9403, 2.1697, -0.9606]; % Coefficients of AR(4) process
a = [1 -a];
x = filter(1,a,w);
xacf = xcorr(x); % Autocorrelation of AR(4) process
dft = fft(xacf);
EmpPSD = abs(dft/length(dft)).^ 2; % Empirical PSD obtained from data
ThePSD = abs(freqz(1,a,N,1)).^ 2; % Theoretical PSD obtained from model
```

Imperial College London © D. P. Mandic

Normal equations for the autocorrelation coefficients

For the autocorrelation coefficients

$$\rho_k = r_{xx}(k)/r_{xx}(0)$$

we have

$$\rho_{1} = a_{1} + a_{2}\rho_{1} + \dots + a_{p}\rho_{p-1}$$

$$\rho_{2} = a_{1}\rho_{1} + a_{2} + \dots + a_{p}\rho_{p-2}$$

$$\vdots = \vdots$$

$$\rho_{p} = a_{1}\rho_{p-1} + a_{2}\rho_{p-2} + \dots + a_{p}$$

When does the sequence $\{\rho_0, \rho_1, \rho_2, \ldots\}$ vanish?

Homework: Try command **xcorr** in Matlab

Yule–Walker modelling in Matlab

In Matlab – Power spectral density using Y–W method pyulear

```
Pxx = pyulear(x,p)
[Pxx,w] = pyulear(x,p,nfft)
[Pxx,f] = pyulear(x,p,nfft,fs)
[Pxx,f] = pyulear(x,p,nfft,fs,'range')
[Pxx,w] = pyulear(x,p,nfft,'range')
```

Description:

```
Pxx = pyulear(x,p)
```

implements the Yule-Walker algorithm, and returns Pxx, an estimate of the power spectral density (PSD) of the vector x.

To remember for later \rightarrow This estimate is also an estimate of the maximum entropy.

See also aryule, lpc, pburg, pcov, peig, periodogram

Stochastic modelling: From raw data to ARMA(p,q) proc.

So far, we have assumed the model (AR, MA, or ARMA) and analysed the ACF and PSD based on known model coefficients.

In practice: DATA \hookrightarrow MODEL

This procedure is as follows:

```
* record data x(k)
* find the autocorrelation of the data ACF(x)
* divide by r_xx(0) to obtain correlation coefficients \rho(k)
* write down Yule-Walker equations
* solve for the vector of AR parameters
```

The problem is that we do not know the model order p beforehand. An illustration of the importance of the correct morel order is given in the following example.

Example 9: Sunspot number estimation

consistent with the properties of a second order AR process

Special case #1: AR(1) process (Markov)

For Markov processes, instead of the iid condition, we have the **first order conditional expectation**, that is

 $p(x[n]|x[n-1], x[n-2], \dots, x[0]) = p(x[n]|x[n-1])$

Then $x[n] = a_1 x[n-1] + w[n] = w[n] + a_1 w[n-1] + a_1^2 w[n-2] + \cdots$

Therefore: first order dependence, order-1 memory

- i) For the AR(1) process to be stationary $-1 < a_1 < 1$.
- ii) Autocorrelation Function of AR(1): From the Yule-Walker equations $r_{xx}(k) = a_1 r_{xx}(k-1), \quad k > 0$ $r_0 = a_1 r_{xx}(1) + \sigma_w^2, \quad k = 0$

In terms of the correlation coefficients, $\rho(k) = r(k)/r(0)$, with $\rho_0 = 1$

$$\rho_k = a_1^k, \quad k > 0$$

Notice the difference in the behaviour of the ACF for a_1 positive and negative

Variance and power spectrum of AR(1) process

Both can be calculated directly from the general expression for the variance and spectrum of AR(p) processes.

 Variance: Also from a general expression for the variance of linear processes from Lecture 1

$$\sigma_x^2 = \frac{\sigma_w^2}{1 - \rho_1 a_1} = \frac{\sigma_w^2}{1 - a_1^2}$$

• **Power spectrum:** Notice how the flat PSD of WGN is shaped according to the position of the pole of AR(1) model (Low-Pass for $0 < a_1 < 1$ and High-Pass for $-1 < a_1 < 0$)

$$P_{xx}(f) = \frac{2\sigma_w^2}{\left|1 - a_1 e^{-j2\pi f}\right|^2} = \frac{2\sigma_w^2}{1 + a_1^2 - 2a_1 \cos(2\pi f)}$$

Example 10 a): ACF and spectrum of AR(1) for $a = \pm 0.8$ $a < 0 \rightarrow$ **High Pass** $a > 0 \rightarrow$ **Low Pass**

London

Statistical Signal Processing & Inference 32

Example 10 b): Model order of a financial time series (the

'correct' and 'time-reversed' time series)

Autoregressive coefficients: AR(1): $\mathbf{a} = [0.9994]$ AR(2): $\mathbf{a} = [.9994, -.0354]$ AR(3): $\mathbf{a} = [.9994, -.0354,$ -.0024AR(4): $\mathbf{a} = [.9994, -.0354,$ -.0024,.0129AR(5): $\mathbf{a} = [.9994, -.0354,$ -.0024, .0129, -.0129AR(6): $\mathbf{a} = [.9994, -.0354]$ -.0024, .0129, -.0129, -.0172]

Imperial College ©

D. P. Mandic

Special case #2: Second order autoregressive processes, p = 2, q = 0, hence the notation AR(2)

The input–output functional relationship is given by ($w[n] \sim$ any white noise)

$$x[n] = a_1 x[n-1] + a_2 x[n-2] + w[n]$$

$$X(z) = (a_1 z^{-1} + a_2 z^{-2}) X(z) + W(z)$$

$$\Rightarrow H(z) = \frac{X(z)}{W(z)} = \frac{1}{1 - a_1 z^{-1} - a_2 z^{-2}}$$

$$H(\omega) = H(e^{j\omega}) = \frac{1}{1 - a_1 e^{-j\omega} - a_2 e^{-2j\omega}}$$

Y-W equations for p=2

$$\rho_1 = a_1 + a_2 \rho_1$$

 $\rho_2 = a_1 \rho_1 + a_2$

when solved for a_1 and a_2 , we have

$$a_1 = \frac{\rho_1(1-\rho_2)}{1-\rho_1^2} \qquad a_2 = \frac{\rho_2 - \rho_1^2}{1-\rho_1^2}$$

Connecting a's and ρ 's

$$\rho_1 = \frac{a_1}{1 - a_2}$$
$$\rho_2 = a_2 + \frac{a_1^2}{1 - a_2}$$

Since $\rho_1 < \rho(0) = 1 \Leftrightarrow$ a stability condition on a_1 and a_2

Imperial College London © D. P. Mandic

Variance and power spectrum

Both readily obtained from the general AR(2) process equation!

Variance

$$\sigma_x^2 = \frac{\sigma_w^2}{1 - \rho_1 a_1 - \rho_2 a_2} = \left(\frac{1 - a_2}{1 + a_2}\right) \frac{\sigma_w^2}{(1 - a_2)^2 - a_1^2}$$

Power spectrum

$$P_{xx}(f) = \frac{2\sigma_w^2}{|1 - a_1 e^{-j2\pi f} - a_2 e^{-j4\pi f}|^2} \\ = \frac{2\sigma_w^2}{1 + a_1^2 + a_2^2 - 2a_1(1 - a_2\cos(2\pi f) - 2a_2\cos(4\pi f))}, \quad 0 \le f \le 1/2$$

Stability conditions \rightsquigarrow (Condition 1 can be obtained from the denominator of variance, Condition 2 from the expression for ρ_1 , etc.)

Condition 1: $a_1 + a_2 < 1$ Condition 2: $a_2 - a_1 < 1$ Condition 3: $-1 < a_2 < 1$

This can be visualised within the so-called "stability triangle"

Stability triangle

- i) **Real roots** Region 1: Monotonically decaying ACF
- ii) Real roots Region 2: Decaying oscillating ACF
- iii) Complex roots Region 3: Oscillating pseudo-periodic ACF
- iv) Complex roots Region 4: Pseudo-periodic ACF

Example 11: Stability triangle and ACFs of AR(2) signals

Determining regions in the stability triangle

let us examine the autocorrelation function of AR(2) processes

The ACF

$$\rho_k = a_1 \rho_{k-1} + a_2 \rho_{k-2} \qquad k > 0$$

- **Real roots:** \Rightarrow ($a_1^2 + 4a_2 > 0$) ACF \leftrightarrow mixture of damped exponentials
- Complex roots: \Rightarrow $(a_1^2 + 4a_2 < 0) \Rightarrow$ ACF exhibits a pseudo-periodic behaviour

$$\rho_k = \frac{D^k \sin(2\pi f_0 k + \Phi)}{\sin \Phi}$$

D - damping factor, of a sinewave with frequency f_0 and phase Φ

$$D = \sqrt{-a_2}$$
$$\cos(2\pi f_0) = \frac{a_1}{2\sqrt{-a_2}}$$
$$\tan(\Phi) = \frac{1+D^2}{1-D^2}\tan(2\pi f_0)$$

Imperial College London

Model order selection: Partial autocorrelation function

Consider an earlier example using a slightly different notation for AR coefficients

Partial autocorrelation function: Motivation see Appendix for more detail

Notice: ACF of AR(p) infinite in duration, **but** can by be described in terms of p nonzero functions ACFs.

Denote by a_{kj} the *j*th coefficient in an autoregressive representation of order k, so that a_{kk} is the last coefficient. Then

$$\rho_j = a_{kj}\rho_{j-1} + \dots + a_{k(k-1)}\rho_{j-k+1} + a_{kk}\rho_{j-k} \qquad j = 1, 2, \dots, k$$

leading to the Yule–Walker equations, which can be written as

$$\begin{bmatrix} 1 & \rho_1 & \rho_2 & \cdots & \rho_{k-1} \\ \rho_1 & 1 & \rho_1 & \cdots & \rho_{k-2} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \rho_{k-1} & \rho_{k-2} & \rho_{k-3} & \cdots & 1 \end{bmatrix} \begin{bmatrix} a_{k1} \\ a_{k2} \\ \vdots \\ a_{kk} \end{bmatrix} = \begin{bmatrix} \rho_1 \\ \rho_2 \\ \vdots \\ \rho_k \end{bmatrix}$$

The only difference from the standard Y-W equations is the use of the symbols a_{ki} to denote the AR coefficient $a_i \hookrightarrow k$ indicating the model order

Finding partial ACF coefficients

Solving these equations for $k = 1, 2, \ldots$ successively, we obtain

$$a_{11} = \rho_1, \qquad a_{22} = \frac{\rho_2 - \rho_1^2}{1 - \rho_1^2}, \qquad a_{33} = \frac{\begin{vmatrix} 1 & \rho_1 & \rho_1 \\ \rho_1 & 1 & \rho_2 \\ \rho_2 & \rho_1 & \rho_3 \end{vmatrix}}{\begin{vmatrix} 1 & \rho_1 & \rho_2 \\ \rho_1 & 1 & \rho_1 \\ \rho_2 & \rho_1 & 1 \end{vmatrix}, \quad \text{etc}$$

- The quantity a_{kk} , regarded as a function of the model order k, is called the **partial autocorrelation function (PAC)** (see Appendix for more detail)
- For an AR(p) process, the PAC a_{kk} will be nonzero for $k \leq p$ and zero-valued for k > p \hookrightarrow indicates the order of an AR(p) process.

In practice, we introduce a small threshold, as for real world data it is difficult to guarantee that $a_{kk} = 0$ for k > p. (see your Coursework)

Example 13: Work by Yule \hookrightarrow model of sunspot numbers

Recorded for > 300 years. To study them in 1927 Yule invented the AR(2) model

We first center the data, as we do not wish to model the DC offset (determinisic component), but the stochastic component (AR model driven by white noise)! Using the Y-W equations we obtain: $\mathbf{a}_1 = [0.9295]$ $\mathbf{a}_2 = [1.4740, -0.5857]$ $\mathbf{a}_3 = [1.5492, -0.7750, 0.1284]$ $\mathbf{a}_4 = [1.5167, -0.5788, -0.2638, 0.2532]$ $\mathbf{a}_5 = [1.4773, -0.5377, -0.1739, -0.1739]$ 0.0174, 0.1555 $\mathbf{a}_6 = [1.4373, -0.5422, -0.1291,$ 0.1558, -0.2248, 0.2574] See also Slide 9

Example 13 (contd.): Model order for sunspot numbers

After k = 2 the partial correlation function (PAC) is very small, indicating p = 2

The broken red lines denote the 95% confidence interval which has the value $\pm 1.96/\sqrt{N}$, and where $PAC \approx 0$

Example 14: Model order for an AR(3) process

An AR(3) process realisation, its ACF, and partial autocorrelation (PAC)

After lag k = 3, the PAC becomes very small (broken line \rightsquigarrow conf. int.)

Example 15: The Partial Correlation view \hookrightarrow **model order of a financial time series** (the 'correct' and 'time-reversed' time series)

Partial correlations: AR(1): $\mathbf{a} = [0.9994]$ AR(2): $\mathbf{a} = [.9994, -.0354]$ AR(3): $\mathbf{a} = [.9994, -.0354,$ -.0024AR(4): $\mathbf{a} = [.9994, -.0354,$ -.0024,.0129AR(5): $\mathbf{a} = [.9994, -.0354,$ -.0024, .0129, -.0129AR(6): $\mathbf{a} = [.9994, -.0354]$ -.0024, .0129, -.0129, -.0172]

AR model based prediction: Importance of model order

For a zero mean process x[n], the best **linear predictor**, in the **mean** square error sense, of x[n] based on $x[n-1], x[n-2], \ldots$ is

$$\hat{x}[n] = a_{k-1,1}x[n-1] + a_{k-1,2}x[n-2] + \dots + a_{k-1,k-1}x[n-k+1]$$

(apply the $E\{\cdot\}$ operator to the general AR(p) model expression, and recall that $E\{w[n]\}=0$)

(Hint: $E\{x[n]\} = \hat{x}[n] = E\{a_{k-1,1}x[n-1] + \dots + a_{k-1,k-1}x[n-k+1] + w[n]\} = a_{k-1,1}x[n-1] + \dots + a_{k-1,k-1}x[n-k+1])$

whether the process is an AR or not

In MATLAB, check the function:

ARYULE

and functions

PYULEAR, ARMCOV, ARBURG, ARCOV, LPC, PRONY

Example 17: AR(1) and AR(3) prediction of COVID-19 data

Example 18: Under– vs Over–fitting a model \hookrightarrow Estimation of the parameters of an AR(2) process

Consider AR(2): x[n] = -0.2x[n-1] - 0.9x[n-2] + w[n], $w[n] \sim \mathcal{N}(0, 1)$ We perform its prediction using AR(1), AR(2) and AR(20) models:

The *higher order* coefficients of the AR(20) model are close to zero and therefore do not contribute significantly to the estimate, while the AR(1) does not have sufficient degrees of freedom. (see also Appendix 3)

Effects of over-modelling on autoregressive spectra: Spectral line splitting

Consider an AR(2) signal x(n) = -0.9x(n-2) + w(n) with $w \sim \mathcal{N}(0, 1)$. N = 64 data samples, model orders p = 4 (solid blue) and p = 12 (broken green). AR_2_Highpass_Circularity.m

Although the true spectrum has a single spectral peak at $\omega - \pi/2$ (blue), when over-modelling using p = 12 this peak is split into two peaks (green).

Model order selection \hookrightarrow practical issues (see Appendix)

In practice: the greater the model order the greater accuracy & complexity **Q: When do we stop? What is the optimal model order?**

Solution: To establish a trade–off between computational complexity and model accuracy, we introduce a "penalty" for high model orders. Some of the criteria for model order selection are:

MDL: The minimum description length criterion (MDL) (by Rissanen),

AIC: The Akaike information criterion (AIC)

MDL
$$p_{opt} = \min_{p} \left[log(E) + \frac{p * log(N)}{N} \right]$$

AIC $p_{opt} = \min_{p} \left[log(E) + 2p/N \right]$

 $E \rightsquigarrow$ the loss function (typically cumulative squared error), $p \rightsquigarrow$ the number of estimated parameters (model order), $N \rightsquigarrow$ the number of available data points.

Example 19: Model order selection \hookrightarrow **MDL vs AIC**

MDL and AIC criteria for an AR(2) model with $a_1 = 0.5$ $a_2 = -0.3$

Statistical Signal Processing & Inference 53 Moving average processes, MA(q)

A general MA(q) process is given by

$$x[n] = w[n] + b_1 w[n-1] + \dots + b_q w[n-q]$$

Autocorrelation function: The autocovariance function of MA(q) $c_k = E[(w[n] + b_1w[n-1] + \dots + b_qw[n-q]) \times x[n-k]]$ The ACF of an MA process has a cutoff after lag q.

Hence the, for k = 0, the variance of the MA(q) process becomes

$$c_0 = (1 + b_1^2 + \dots + b_q^2)\sigma_w^2$$

Spectrum: All–zero transfer function \Rightarrow struggles to model 'peaky' PSDs $P(f) = 2\sigma_w^2 \left| 1 + b_1 e^{-\jmath 2\pi f} + b_2 e^{-\jmath 4\pi f} + \dots + b_q e^{-\jmath 2\pi q f} \right|^2$

Example 20: Third order moving average MA(3) process

An MA(3) process and its autocorrel. (ACF) and partial autocorrel. (PAC) fns.

After lag k = 3, the PAC becomes very small (broken line \rightsquigarrow conf. int.)

Analysis of nonstationary signals

 Consider a real– world speech signal, and thee different segments with different statistical properties

○DifferentARmodelordersrequiredfordifferentsegmentsofspeech♀→opportunityforcontentanalysis!

 To deal with nonstationarity we need short sliding data windows

London

© D. P. Mandic

Statistical Signal Processing & Inference 56

Example 21: Problems with nonstationary data

The nonstat. air passengers time series has trend, cyclical and seasonal comp.

This is reflected in the autocorrelation and PAC functions (trend, seasonal)

Imperial College London © D. P. Mandic

Dealing with nonstationarity in data: Autoregresive Integrated Moving Average models, ARIMA(p,d,q)

• ARMA models should be used when the data is stationary

• When data shows elements of non-stationarity, a generalisation of ARMA models may be used which accounts for nonstationarity, referred to as the **autoregressive integrated moving average** (ARIMA) model

• The form of ARIMA models is same as that of ARMA models, but with additional differencing of the input data in order to remove elements of non-stationarity (e.g. drifts or trends)

 \circ This differencing corresponds to the "integrated" part of the model \circ ARIMA(p, d, q) means: AR of order p, MA of order q, $d \times$ differentiation

$$y(n) = \sum_{i=1}^{p} a_i y(n-i) + \sum_{j=1}^{q} b_j w(n-j) + w(n)$$

where y(n) is the d-th difference of x(n). Therefore,

• For d = 0, we have y[n] = x[n] • For d = 1, y(n) = x(n) - x(n-1)• For d = 2, that is for an ARIMA(p,2,q) model, we have y(n)=[x(n)-x(n-1)] - [x(n-1)-x(n-2)] = x(n) - 2x(n-1) + x(n-2)Imperial College • D. P. Mandic Statistical Signal Processing & Inference 58

ARMA vs ARIMA prediction of nonstationary dasta

For illustration, we compared the ARMA(2,4) and ARIMA(2,1,4) model

For ARIMA(2,1,4) modelling and subsequent prediction (inference), the airline passenger time series was first differentiated as

$$y(n) = x(n) - x(n-1)$$
 for $n = 1, ..., N-1$

The ARIMA(2,1,4) model was then found, of the form

 $y(n) = a_1 y(n-1) + a_2 y(n-2) + b_1 w(n-1) + \dots + b_4 w(n-4) + w(n)$

Observe that the ARIMA(2,1,4) model was able to deal much better with the nonstationarity of the input, and produce good prediction.

Imperial College London © D. P. Mandic

Example 22: ARIMA prediction of COVID-19 death data

(see Lecture 3 for the Bias–Variance trade–off)

Consider the prediction of COVID-19 death rates in the UK.

 \circ The AR(1) prediction exhibits bias, as the mean of the predicted data (in red) is "off-set" from the mean of true data (in blue) for most of the plot \circ The ARIMA(7,1,1) prediction coincides with the original data in terms of the mean for the whole plot, but exhibits large variability (which do you prefer)

Summary: AR and MA Processes

- A stationary AR(p) process can be represented as an infinite order MA process. A finite MA process has a dual infinite AR process.
- A finite MA(q) process has an ACF that is zero beyond lag q. For an AR process, the ACF is infinite in length and consists of mixture of damped exponentials and/or damped sinusoids.
- Finite MA processes are always stable, and there is no requirement on the coefficients of MA processes for stationarity. For invertibility, the roots of the characteristic equation must lie inside the unit circle.
- AR processes produce spectra with sharp peaks (two poles of A(z) per peak), whereas MA processes cannot produce peaky spectra.

ARMA modelling is a classic technique which has found a tremendous number of practical applications.

Even Large Language Models (LLM) such as ChatGPT perform a form of auto-regression when generating new words.

Summary: Wold's decomposition, ARMA, ARIMA

- Every stationary time series can be represented as a sum of a perfectly predictable process and a feasible moving average process
- Two time series with the same Wold representations are the same, as the Wold representation is unique
- Since any MA process also has an ARMA representation, working with ARMA models is not an arbitrary choice but is physically justified
- The causality and stationarity on ARMA processes depend entirely on the AR parameters and not on the MA parameters
- $\circ\,$ An MA process is not uniquely determined by its ACF
- \circ An AR(p) process is always invertible, even if it is not stationary
- \circ An MA(q) process is always stationary, even if it is non-invertible
- For non-stationary data we may employ ARIMA(p,d,q) models

Recap: Linear systems

Described by their impulse response h(n) or the transfer function H(z)

In the frequency domain (remember that $z = e^{j\theta}$) the transfer function is

$$H(\theta) = \sum_{n=-\infty}^{\infty} h(n)e^{-\eta n\theta} \qquad \{x[n]\} \to \left| \begin{array}{c} \{h(n)\} \\ H(\theta) \end{array} \right| \to \{y[n]\}$$

that is
$$y[n] = \sum_{r=-\infty}^{\infty} h(r)x[n-r] = h * x$$

The next two slides show how to calculate the power of the output, y(k).

Recap: Linear systems – statistical properties \hookrightarrow mean and variance

i) Mean

$$E\{y[n]\} = E\left\{\sum_{r=-\infty}^{\infty} h(r)x[n-r]\right\} = \sum_{r=-\infty}^{\infty} h(r)E\{x[n-r]\}$$

$$\Rightarrow \qquad \mu_y = \mu_x \sum_{r=-\infty}^{\infty} h(r) = \mu_x H(0)$$

[NB: $H(\theta) = \sum_{r=-\infty}^{\infty} h(r)e^{-jr\theta}$. For $\theta = 0$, then $H(0) = \sum_{r=-\infty}^{\infty} h(r)$]

ii) Cross-correlation

$$r_{yx}(m) = E\{y[n]x[n+m]\} = \sum_{r=-\infty}^{\infty} h(r)E\{x[n-r]x[n+m]\}$$

 $= \sum_{r=-\infty}^{\infty} h(r) r_{xx}(m+r) \text{ convolution of input ACF and } \{\mathbf{h}\}\$

 \Rightarrow Cross-power spectrum $S_{yx}(f) = \mathcal{F}(r_{yx}) = S_{xx}(f)H(f)$

Recap: Lin. systems – statistical properties \hookrightarrow output

These are key properties \hookrightarrow used in AR spectrum estimation

From
$$r_{xy}(m) = r_{yx}(-m)$$
 we have
 $r_{xy}(m) = \sum_{r=-\infty}^{\infty} h(r)r_{xx}(m-r)$. Now we write
 $r_{yy}(m) = E\{y[n]y[n+m]\} = \sum_{r=-\infty}^{\infty} h(r)E\{x[n-r]y[n+m]\}$
 $= \sum_{r=-\infty}^{\infty} h(r)r_{xy}(m+r) = \sum_{r=-\infty}^{\infty} h(-r)r_{xy}(m-r)$

by taking Fourier transforms we have

$$S_{xy}(f) = S_{xx}(f)H(f)$$

$$S_{yy}(f) = S_{xy}(f)H(-f) \quad \rightsquigarrow \text{ function of } r_{xx}$$

or

$$\mathbf{S}_{\mathbf{y}\mathbf{y}}(\mathbf{f}) = \mathbf{H}(\mathbf{f})\mathbf{H}(-\mathbf{f})\mathbf{S}_{\mathbf{x}\mathbf{x}}(\mathbf{f}) = |\mathbf{H}(\mathbf{f})|^{2}\mathbf{S}_{\mathbf{x}\mathbf{x}}(\mathbf{f})$$

Output power spectrum = input power spectrum \times squared transfer function

More on Wold Decomposition (Representation) Theorem

Example: A "paradox", can we talk about a deterministic random process

Consider a stochastic process given by

 $x[n] = A\cos[n] + B\sin[n]$

where A, $B \in \mathcal{N}(0, \sigma^2)$ and A is independent of B (A and B are independent normal random variables).

This process is deterministic because it can be written as

$$x[n] = \frac{\sin(2)}{\sin(1)} x[n-1] - x[n-2]$$

that is, based on the history of x[n]. Therefore

$$p(x[n] | x[n-1], x[n-2], \ldots) = \frac{\sin(2)}{\sin(1)} x[n-1] - x[n-2] = x[n]$$

Remember: Deterministic does not mean that x[n] is non-random

Appendix 1: Sunspot numbers (recorded since 1874)

Top: original sunspots N

Middle and Bottom: AR(2) representations

Appendix 2: Model order for an AR(2) process

An AR(2) signal, its ACF, and its partial autocorrelations (PAC)

After lag k = 2, the PAC becomes very small (broken line \rightsquigarrow conf. int.)

Appendix 3: Obtaining the ACF of a general AR(p) process

Consider the AR(p) process, given by $x[n] = a_1 x[n-1] + a_2 x[n-2] + \dots + a_p x[n-p] + w[n]$ To obtain the autocorrelation function of this AR process, multiply the above equation by x[n-k] to obtain (recall that r(-m) = r(m)) $x[n-k]x[n] = a_1x[n-k]x[n-1] + a_2x[n-k]x[n-2] + \cdots$ $+a_n x[n-k]x[n-p] + x[n-k]w[n]$ Apply the statistical expectation operator (the coefficients a_i go in front) $E\{x[n-k]x[n]\} = a_1 E\{x[n-k]x[n-1]\} + a_2 E\{x[n-k]x[n-2]\} + \cdots$ $r_{xx}(\mathbf{k}-1)$ $r_{xx}(\dot{k}-2)$ $r_{rr}(k)$ $+a_p \underbrace{E\{x[n-k]x[n-p]\}}_{k=1} + \underbrace{E\{x[n-k]w[n]\}}_{k=1}$ $r_{xx}(k-p)$ $r_{xw}(k)=0$ If $r_{xw}(k) = 0$ since $x[n-k] = a_1 x[n-k-1] + \dots + a_p x[n-k-p] + w[n-k]$. As $w[n-x] \perp w[n]$, then $E\{x[n-k]w[n]\}$ vanishes for k > 0, to give $r_{xx}(k) = a_1 r_{xx}(k-1) + a_2 r_{xx}(k-2) + \dots + a_p r_{xx}(k-p),$ k > 0

Appendix 4: More on the Partial Autocorrelation Function (PACF)

The PACF of a stationary process is a vector, π , defined as

$$\pi(k) = \begin{cases} \pi(0) = 1\\ \pi(k) = a_{kk}, & \text{for } k \ge 1 \end{cases}$$

where a_{kk} is the last component of $\mathbf{a}_k = [a_{k1}, a_{k2}, \dots, a_{kk}]^T, k = 1, 2, \dots p$ which are calculated from $\mathbf{a}_k = \mathbf{R}_k^{-1}\mathbf{r}_k$ (Yule-Walker, see Slide 23)

It is possible to show that its value $\pi(k) = a_{kk}$, for $k \ge 1$ is equivalent to the correlation coefficient between the residuals of the regressions

$$x(n) - \hat{x}(n) = x(n) - E\{x(n) | x(n-1), \dots, x(n-k+1)\} \text{ and}$$
$$x(n-k) - \hat{x}(n-k) = x(n-k) - E\{x(n-k) | x(n-k+1), \dots, x(n-1)\}$$

 $\begin{array}{ll} & \hline & \pi(k) \text{ (or equally the AR coefficient } a_{kk} \text{) measures the linear link between} \\ & x(n) \text{ and } x(n-k), \text{ once we have removed the influence of} \\ & x_{n-1}, \ldots, x_{n-k+1}, \text{ i.e. } & a_{kk} = corr(x(n) - \hat{x}(n), x(n-k) - \hat{x}(n-k)). \end{array}$

Appendix 5: Confidence intervals for PACFs (intuition)

Quenouille (1949) showed that on the hypothesis that the process is AR(p), the estimated partial autocorrelations of order p + 1, and higher, are approximately independently and normally distributed with zero mean. With N observations, we then have $var(\hat{a}_{kk}) \approx 1/N$, $k \geq p+1$. Thus, the standard error (SE) of the estimated PAC \hat{a}_{kk} is

$$SE(\hat{a}_{kk}) = \hat{\sigma}(\hat{a}_{kk}) \approx 1/\sqrt{N}, \quad k \ge p+1.$$

Intuition: Let us establish whether a time series, $\{x_1, \ldots, x_N\}$, is an independent identically distributed process, that is, $x \sim i.i.d.(0,\sigma^2)$ To achieve this, we need a decision rule, for example

Reject the null hypothesis $H_0: \rho_k = 0$ if $|\hat{\rho}_k| > c$, with c a constant. Constant c is a threshold, arising e.g. from a statistical significance test $P(|\hat{\rho}_k| > c|H_0) = 0.05 \quad \Rightarrow \quad P(|\hat{\rho}_k| > c|H_0) = 1 - P(|\hat{\rho}_k| \le c|H_0) = 0.05$ This implies that $P(|\hat{\rho}_k| \le c|H_0) = P(-c\sqrt{N} \le \sqrt{N}\hat{\rho}_k \le c\sqrt{N}) = 0.95$

Appendix 5: Confidence intervals for PACFs (intuition)

If x_n is $i.i.d.(0, \sigma^2)$, then $\sqrt{N}\hat{\rho}_k \to \mathcal{N}(0, 1)$ and, for large N, a normal distribution is a good approximation to the true distribution of $\sqrt{N}\hat{\rho}_k$. s.t.

 $P(-c\sqrt{N} \le \sqrt{N}\hat{\rho}_k \le c\sqrt{N}) = 0.95 \quad \text{iff} \quad c\sqrt{N} = 1.96 \quad \Rightarrow \quad c = \frac{1.96}{\sqrt{N}}$

We can reject H_0 if $|\hat{\rho}_k| > 1.96/\sqrt{N}$ that is, if $\hat{\rho}_k \notin [-1.96/\sqrt{N}, 1.96/\sqrt{N}]$

In a two-tailed test, the rejection region for a significance level of 0.05 is at both ends of the distribution (in our case Gaussian), and amounts to up to 5% of the area under the curve (white regions).

If the data, x_1, \ldots, x_N were indeed generated by an *i.i.d.* process, then \approx 95% of sample ACFs, $\hat{\rho}_1, \ldots, \hat{\rho}_n$, should be within the bounds $\pm 1.96/\sqrt{N}$. In other words, about 5% of the sample correlations should be outside the broken red lines in the PACF plots. For example, if 20 values of $\hat{\rho}_k$ are calculated, then only one of its values should lie outside these limits.
Appendix 5: Confidence intervals for PACFs (intuition)

The PACF basically finds correlation between the residuals at time n and ľ ôr time n-k (after removing the effects which are already explained by the earlier lags).

This is why it is called "partial" as the already found variations are removed before calculating the next correlation.

If there is any hidden information left in the residual, we might have a good correlation at the next lag, so we keep exploring along the lags.

Too many correlated features are not desirable, as this can create 1 T collinearity issues \rightarrow we should retain only the relevant features.

The null hypothesis is the "default" assumption that there has been no change in statistical behaviour.

To determine whether a result is statistically significant, we calculate a *p*-value, which is the probability of a more extreme statistical behaviour given that the null hypothesis is true.

The null hypothesis is rejected if the p-value is less than (or equal to) a predetermined level – the significance level – which is usually set at 5%.

Appendix 6: A note on over-parametrisation

Consider the linear stochastic process given by

$$x[n] = x[n-1] - 0.16x[n-2] + w[n] - 0.8w[n-1]$$

It clearly has an ARMA(2,1) form. Consider now its coefficient vectors written as polynomials in the z-domain:

$$a(z) = 1 - z^{-1} + 0.16z^{-2} = (1 - 0.8z^{-1})(1 - 0.2z^{-1})$$

 $b(z) = 1 - 0.8z^{-1}$

These polynomials have a common factor $(1 - 0.8z^{-1})$, and therefore after cancelling these terms, we have the resulting lower-order polynomials:

$$a(z) = 1 - 0.2z^{-1}$$

 $b(z) = 1$

The above process is therefore an AR(1) process, given by

$$x[n] = 0.2x[n-1] + w[n]$$

and the original ARMA(2,1) version was over-parametrised.

Appendix 7: More on model order selection

A criterion is said to be **consistent** if the correct model is chosen with probability one as the number of data points asymptotically approaches ∞ .

 \circ MDL is consistent whereas AIC is not.

 \circ Hannan and Quinn (1979) proposed the Hannan-Quinn information criterion (HQC) as a means of improving the consistency of AIC.

 Small-sample properties of AIC lead to over-estimating the model order. Hurvich and Tsai (1989) derived a 'corrected' AIC, referred to as AICc, in order to compensate for the small-sample over-fitting.

More detail in e.g. "Regression and Time Series Model Selection" by McQuarrie and Tsai.

$$\mathsf{MDL} = \log E_p + \frac{p \log N}{N} \qquad \qquad \mathsf{AIC} = \log E_p + \frac{2p}{N} \tag{1}$$

$$HQC = \log E_p + \frac{2p \log \log N}{N} \qquad AICc = AIC + \frac{2p(p+1)}{N-p-1} \qquad (2)$$

where p is the model order, E_p is the loss function for the model with p parameters and N is the number of estimated data points.

Appendix 7: More on model order selection

The results below show that the AIC_c criterion was able to identify the most parsimonious model order of p = 2,

Figure 1: Information criteria for AR model order selection, with cumulative squared error as the loss function. A short segment of an AR(2) process was considered, which affected the reliability of these information criteria.

Appendix 8: Something to think about ...

 What would be the properties of a multivariate (MV) autoregressive, say MVAR(1), process, where the quantities w, x, a now become matrices, that is

$$\mathbf{X}(n) = \mathbf{A}\mathbf{X}(n-1) + \mathbf{W}(n)$$

- Would the inverse of the multichannel correlation matrix depend on 'how similar' the data channels are? Explain also in terms of eigenvalues and 'collinearity'.
- Threshold autoregressive (TAR) models allow for the mean of a time series to change along the blocks of data. What would be the advantages of such a model?
- Try to express an AR(p) process as a state-space model. What kind of the transition matrix between the states do you observe?

Consider also: Fourier transform as a filtering operation We can see FT as a convolution of a complex exponential and the data (under a mild assumption of a one-sided h sequence, ranging from 0 to ∞)

1) Continuous FT. For a continuous FT $F(\omega) = \int_{-\infty}^{\infty} x(t)e^{-j\omega t}dt$ Let us now swap variables $t \to \tau$ and multiply by $e^{j\omega t}$, to give

$$e^{j\omega t} \int x(\tau) e^{-j\omega \tau} d\tau = \int x(\tau) \underbrace{e^{j\omega(t-\tau)}}_{h(t-\tau)} d\tau = x(t) * e^{j\omega t} \quad (=x(t) * h(t))$$

2) Discrete Fourier transform. For DFT, we have a filtering operation

$$X(k) = \sum_{n=0}^{N-1} x(n) e^{-j\frac{2\pi}{N}nk} = \underbrace{x(0) + W \Big[x(1) + W \big[x(2) + \cdots \Big]}_{\text{cumulative add and multiply}} \qquad W = e^{-j\frac{2\pi}{N}n}$$

with the transfer function (large N) $H(z) = \frac{1}{1-z^{-1}W} = \frac{1-z^{-1}W^*}{1-2\cos\theta_L z^{-1}+z^{-2}}$

exp(jwt) discrete time case x[n]DFT (t)*exp(jwt) x(t)DFT W continuous time case
